

# FA5331P(M)/FA5332P(M)

Bipolar IC  
For Power Factor Correction

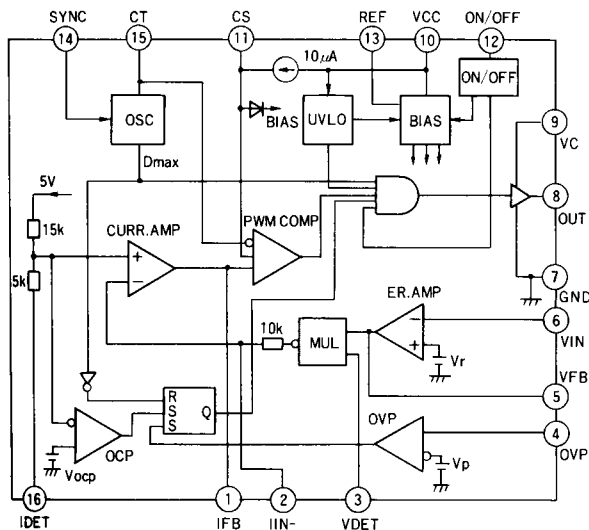

## ■ Description

FA5331P(M) and FA5332P(M) are control ICs for a power factor correction system. These ICs use the average current control system to ensure stable operation. With this system, a power factor of 99% or better can be achieved. FA5331P(M) is a 1st generation IC and FA5332P(M) is 2nd generation IC which light-load characteristics are improved.

## ■ Features

- Drive circuit for connecting a power MOS-FET( $I_o = \pm 1.5A$ )
- Pulse-by-pulse overcurrent and overvoltage limiting function
- Output ON/OFF control function by external signals
- External synchronizing signal terminal for synchronous operation with other circuits
- Undervoltage malfunction prevention function
- Low standby current (90 $\mu$ A typical) for simple start-up circuit
- 16-pin package (DIP/SOP)
- $\pm 2\%$  accuracy reference voltage for setting DC output and overvoltage protection [FA5332P(M) only]
- When there is a possibility of light-load operation, FA5332P(M) is suitable.

## ■ Block diagram

Pin No.	Pin symbol	Description
1	IFB	Current error amplifier output
2	IIN-	Inverting input to current error amplifier
3	VDET	Multiplier input
4	OVP	Overvoltage protection input
5	VFB	Voltage error amplifier output
6	VIN-	Inverting input to voltage error amplifier
7	GND	Ground
8	OUT	Output
9	VC	Power supply to output circuit
10	VCC	Power supply
11	CS	Soft-start
12	ON/OFF	Output ON/OFF control input
13	REF	Reference voltage
14	SYNC	Oscillator synchronization input
15	CT	Oscillator timing capacitor and resistor
16	IDET	Non-inverting input to current error amplifier

■ Description of each circuit

1. Oscillator section

This section outputs sawtooth waves oscillating between 0.15 and 3.55V using the capacitor charge and discharge characteristics. Figure 1 shows how to connect the required external components to this circuit. The oscillation frequency is determined by the  $C_T$  and  $R_T$  values. The relationship between the  $C_T$  and  $R_T$  values is shown in characteristic curves. Pin 14 (SYNC) is a synchronizing input terminal whose threshold voltage is about 1V. As Fig. 1 shows, input rectangular synchronizing signal waves to pin 14 through an RC circuit. Set the free-running frequency about 10% lower than the synchronizing signal frequency. Connect a clamp diode (D1) to prevent an unwanted current inside the IC.

Fig. 1 Oscillator

2. Voltage error amplifier and overvoltage limiting circuit

The voltage error amplifier forms a voltage feedback loop to keep the output voltage stable. The positive input terminal of this amplifier is connected to the reference voltage ( $V_r$ ). Fig. 2 shows how to connect the required external components to this circuit.

The output voltage ( $V_o$ ) is as follows:

$$V_o = \frac{R1 + R2}{R1} \cdot V_r \dots\dots\dots (1)$$

FA5331:  $V_r=1.54V$ (typ.)  
 FA5332:  $V_r=1.55V$ (typ.)

Connect a resistor and a capacitor in parallel across error amplifier output pin 5 and error amplifier negative input pin 6 to set the voltage gain ( $A_v$ ). The  $A_v$  value is as follows:

$$A_v = \frac{R4}{R3 (1 + j\omega C1 \cdot R4)} \dots\dots\dots (2)$$

Error amplifier cutoff frequency ( $f_c$ ) is as follows:

$$f_c = \frac{1}{2\pi C1 \cdot R4} \dots\dots\dots (3)$$

If 100 or 120Hz ripples appear at the error amplifier output, the active filter does not operate stably. To ensure stable operation, set the  $f_c$  value to about 1Hz.

An overvoltage detection comparator (C1) is built in to limit the voltage if the output voltage exceeds the design value. The reference input voltage ( $V_p$ ) is as follows:

$$V_p = \alpha \cdot V_r \dots\dots\dots (4)$$

$\alpha = 1.065$

The connections shown in Fig. 2 limit the output voltage to  $\alpha$  times the design value.

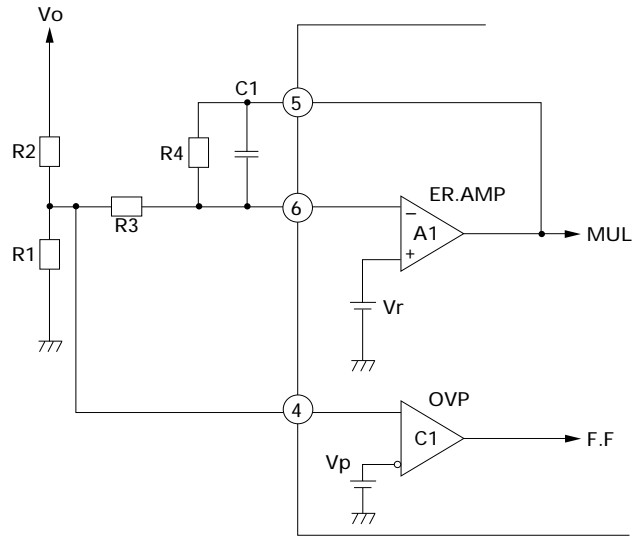

Fig. 2 Voltage error amplifier and overvoltage limiting circuit

**3. Current error amplifier and overcurrent limiting circuit**

The current error amplifier forms a current loop to change the input circuit current into sinusoidal waves. As Fig. 3 shows, the multiplier output is connected to pin 2 (IIN -) through a resistor (RA) to input the reference current signal. Pin 16 (IDET) is a current input terminal. Design the circuit so that the voltage at pin 16 will be within the range from 0 (GND potential) to -1.0V. Connect a phase correction resistor and capacitors across pin 1 (amplifier output) and pin 2. See Fig. 4 for the expected gain characteristics of the circuit shown in Fig. 3.

Here,

$$Z = \frac{1}{2\pi R5 \cdot C3} \dots\dots\dots (5)$$

$$P = \frac{1}{2\pi R5 \cdot C} \dots\dots\dots (6)$$

$$C = \frac{C2 \cdot C3}{C2 + C3}$$

The voltage gain (G1) between Z and P of the circuit (gain between pins 16 and 1) is given as follows:

$$G1 = 20 \cdot \log_{10} \left\{ 0.75 \left( \frac{R5}{RA} + 1 \right) \right\} \dots\dots\dots (7)$$

Ensure an adequate phase margin by selecting C1 and C2 so that the p/z ratio is about 10. The current error amplifier output is used as an input to the comparator for PWM.

The overcurrent detection comparator (C2) limits an overcurrent. The threshold voltage for overcurrent detection at pin 16 is -1.15V for FA5331 and -1.10V for FA5332. Connect noise filters Rn and Cn to prevent the voltage at pin 16 from fluctuating due to noise, causing the comparator to malfunction. For Rn, select a resistor of up to 100Ω for FA5331 and up to 27Ω for FA5332. (See P64, 4. No-load operation )

**4. Comparator for PWM**

Figure 5 shows the comparator for PWM. When the oscillator output (Va) is smaller than the current error amplifier output (Vc), the comparator output is high and the output ON signal is generated at pin 8. Pin 11 (CS) is a terminal for soft start. This terminal charges capacitor C4 with the internal constant current (10μA) for a soft start. Priority is given to Vb and Vc whichever is lower.

**5. Multiplier**

The multiplier generates a reference current signal. Input a fully rectified sinusoidal signal voltage into pin 3 (VDET). Design the circuit to keep the peak voltage at pin 3 within a range from 0.65V to 2V for FA5331 and 0.65V to 2.4V for FA5332. The multiplier output voltage (Vm) is roughly given as follows (see Fig. 6):

$$Vm = 1.25 - (Ve - 1.55) \cdot Vs \dots\dots\dots (8)$$

As Fig. 3 shows Vm is internally connected to pin 2 (IIN-) of the current error amplifier A2 through a 10kΩ resistor. (See the characteristic curve, page 66 for the input and output characteristics of the multiplier.)

**Fig. 3 Current error amplifier and overcurrent limiting circuit**

**Fig. 4 Voltage gain-frequency**

**Fig. 5 PWM comparator**

**Fig. 6 Multiplier**

**6. ON/OFF control input circuit**

Figure 7 shows the ON/OFF control input circuit. If pin 12 is set to the high level (enable), this IC outputs pulses from the OUT pin. If pin 12 is set to the low level (disable), the internal bias power (reference voltage) goes off and the IC current consumption becomes about 1/10 that of its ON state. The output level of pin 11 (CS for soft start) also goes low.

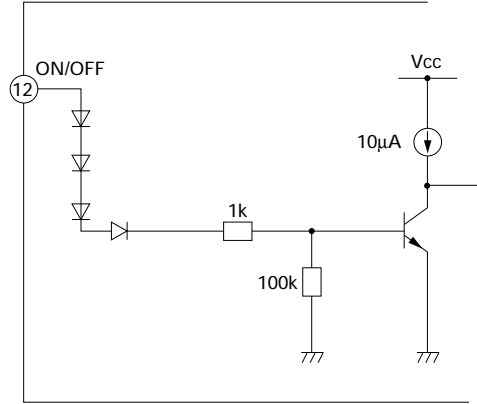

**7. Output circuit**

As Fig. 8 shows, pin 9 is configured as the high power terminal (VC), independent of the IC power terminal (VCC). This pin allows an independent drive resistance when the power MOSFET is ON and OFF. If the drive resistances in the ON and OFF states are Rg (on) and Rg (off), the following formulas can be used to determine the total gate resistance

Rg:  
 $Rg (on) = Rg1 + Rg2 \dots\dots\dots (9)$

$Rg (off) = Rg2 \dots\dots\dots (10)$

In the standby state, the output level of pin 8 is held low. If the potential at the drain terminal of the power MOSFET fluctuates, the gate-drain capacitance may drive the IC output voltage at pin 8 to below 0. Once the voltage at pin 8 reaches -0.6V, an unwanted current flows in the IC and a large abnormal current flows in the output circuit when the output transistor is turned on. To prevent this, connect a Schottky diode across the gate and source of the power MOSFET.

**Fig. 7 ON/OFF control input circuit**

**Fig. 8 Output circuit**

■ Design advice

1. Start circuit

Figure 9 shows a sample start circuit. Since the IC current while the Vcc pin voltage rises from 0V to V<sub>THON</sub> is as small as 90μA (typ.), the power loss in resistor R<sub>A</sub> is small. If an additional winding is prepared in the voltage step-up inductor (L), power to the control circuit can be supplied from this circuit. However, the voltage must be stabilized by a regulator circuit (REG) to prevent an excess rise of the IC supply voltage (Vcc). Use fast or ultra-fast rectifier diodes for the rectifier circuit (DB1) of the winding for high-frequency operation.

2. Current sensing resistor

The current sensing resistor (R<sub>s</sub>) detects the current in the inductor. R<sub>s</sub> is used to make the input current sinusoidal. The current in the inductor produces a negative voltage across R<sub>s</sub>. The voltage is input to IC pin 16 (IDET). Determine the value of R<sub>s</sub> so that the peak voltage of the IDET pin is -1V.

$$R_s = \frac{V_{in}}{\sqrt{2} \cdot P_{in}} \dots\dots\dots (11)$$

V<sub>in</sub>: Minimum AC input voltage (effective value) [V]  
 P<sub>in</sub>: Maximum input power [W]

Since the threshold voltage of the overcurrent limiting circuit (pin 16) is -1.15V for FA5311 for and -1.10V for FA5332, the peak input current limit (i<sub>p</sub>) is determined by:

$$\text{FA5331: } i_p = \frac{1.15}{R_s} \dots\dots\dots (12)$$

$$\text{FA5332: } i_p = \frac{1.10}{R_s}$$

3. Voltage step-up type converter

Figure 9 shows the basic circuit of a voltage step-up type converter which is used as a power factor correction.

(a) Output voltage

For stable operation, set the output voltage to be 10V or more over the peak value of the maximum input voltage. When using this IC for an active filter, set the output voltage (V<sub>o</sub>) as follows:

$$V_o \geq \sqrt{2} \cdot V_{in} + 10V \dots\dots\dots (13)$$

V<sub>in</sub>: Maximum AC input voltage [V]  
 (effective value of sinusoidal wave)

(b) Voltage step-up inductor

When using a voltage step-up converter in continuous current mode, the ratio of inductor current ripple to the input peak current is set to about 20%. Determine the inductance as follows:

$$L \geq \frac{V_{in}^2 (V_o - \sqrt{2} \cdot V_{in})}{\gamma \cdot f_s \cdot P_{in} \cdot V_o} \dots\dots\dots (14)$$

V<sub>in</sub>: Minimum AC input voltage (effective value) [V]  
 γ: Ratio of inductor current ripple (peak to peak value) to the input peak current (about 0.2)  
 f<sub>s</sub>: Switching frequency [Hz]  
 P<sub>in</sub>: Converter's maximum input power [W]

As the characteristic curves on page 66 show, the peak voltage at pin 3 should be at least 0.65V, even when the AC input voltage is minimal. Considering this, determine R<sub>6</sub> and R<sub>7</sub> shown in Fig. 6.

Fig. 9 Start circuit

Example: FA5332

When V<sub>in</sub> is 85V and P<sub>in</sub> is 300W, the formulas of (11) and (12) can be calculated as:

$$R_s = \frac{85}{\sqrt{2} \cdot 300} = 0.2 \text{ [ } \Omega \text{ ]}$$

$$i_p = \frac{1.10}{0.2} = 5.5 \text{ [ A ]}$$

And,

$$\sqrt{2} \cdot 85 \cdot \frac{R_6}{R_6 + R_7} = 0.65 \text{ [ V ]}$$

If R<sub>6</sub> is set to 2.7kΩ to satisfy these formulas, R<sub>7</sub> becomes 480kΩ.

Example:

When V<sub>in</sub> is 85V, V<sub>o</sub> is 385V, and γ is 0.2, the formula of (14) can be calculated as:

$$L \geq \frac{2.48 \times 10^4}{f_s \cdot P_{in}} \text{ [ H ]} \dots\dots\dots (15)$$

(c) Smoothing capacitor

When a voltage step-up converter is used in a power factor correction circuit, the input current waveform is regulated to be in-phase with the input voltage waveform. Therefore, ripple noise of twice the input line frequency appears at the output. The output voltage (v<sub>o</sub>) is represented as:

$$v_o = V_o - \frac{I_o}{2 \cdot \omega_o \cdot C} \cdot \sin 2 \omega_o t \dots\dots\dots (16)$$

V<sub>o</sub>: Average output voltage  
 I<sub>o</sub>: Output current  
 ω<sub>o</sub>: 2π f<sub>o</sub> (f<sub>o</sub>: Input power frequency, 50 or 60Hz)  
 C: Smoothing capacitor value

Therefore, the peak-to-peak value of the output ripple voltage V<sub>rp</sub> is given by:

$$V_{rp} = \frac{I_o}{\omega_o C} \dots\dots\dots (17)$$

Using formula (17), determine the necessary C value.

**4. No-load operation**

The following condition should be met to prevent from overvoltage and audible noise during no-load or light-load operation.

**For FA5331 (Fig.10)**

$$0.85 \cdot \alpha \leq R_{OFST}(k\Omega) \leq \alpha$$

where,  $\alpha = \frac{(3.5 \cdot 10^3 - 0.26 \cdot R_n) \cdot 12}{42 + 0.26 \cdot R_n}$

and,  $R_n \leq 100\Omega$

and, Rx: don't connect.

- You must not connect Rx which reduces DC gain of current error amplifier.
- You can connect R5 which is series with capacitor C3.

**For FA5332 (Fig.11)**

$$R_n \leq 27\Omega$$

and, Rx: don't connect.

- You must not connect Rx which reduces DC gain of current error amplifier.
- You can connect R5 which is series with capacitor C3.
- If you connect ROFST, dead time of AC input current will extend.

**5. How to prevent from intermittent switching of low frequency**

An intermittent switching, which frequency is lower than 10Hz, occurs in some applications.

In this case, it is possible to prevent from this intermittent switching to reduce feedback gain by decreasing the resistance of R4. (See Fig. 2)

You must check the effect thoroughly because this intermittent switching depends on load, temperature and input condition.

■ Application circuit

● Example of FA5331 application circuit

● Example of FA5332 application circuit

Parts tolerances characteristics are not defined in the circuit design sample shown above. When designing an actual circuit for a product, you must determine parts tolerances and characteristics for safe and economical operation.
